(54) Title: **WATER RESISTANT INK JET PRINTABLE SHEET**

(57) Abstract: A water resistant coating composition for ink jet recordable substrates having a pH of less than 7, which includes: (a) an aqueous polyurethane dispersion; and (b) an aqueous solution of a nitrogen containing polymeric dye fixative compound. When applied to a suitable substrate, the coating composition allows for the recording of sharp, waterfast images. A coated ink recordable substrate is also disclosed, which includes a substrate having at least one side and at least one side of the substrate has a coating layer derived from the above described coating composition.

**WO 03/011608 A1**

- 1 -

WATER RESISTANT INK JET PRINTABLE SHEETBACKGROUND OF THE INVENTION

The present invention is directed to an ink jet recordable substrate. In particular, the present invention relates to a water-resistant, coated, ink jet recordable substrate. This application is a conversion of United States Provisional Patent Application having Serial No. 60/309,348, filed on August 1, 2001.

It is known in the art to size paper with sizing components for the purpose of retarding or preventing penetration of liquids into the structure. "Internal sizing" consists of introducing sizing materials into the pulp during the paper making operation. The sizing materials are precipitated onto the fibers primarily for the purpose of controlling penetration of liquids into the final dry paper. "Surface sizing" involves the application of dispersions of film-forming substances such as converted starches, gums, and modified polymers, to previously formed paper. Surface sizing imparts strength to the paper.

The use of sized paper to print with an ink jet printer containing predominantly water-based inks may yield imaged papers which have a tendency to curl into tubes. The use of un-sized paper may result migration of the image through the sheet and interference with the image on the other side, if one side of the imaged sheet comes into contact with water,.

Various attempts have been made in the art to overcome the forgoing problems. For example, United States Patent 5,709,976 discloses a paper substrate coated with a hydrophobic barrier layer and an image receiving layer. The hydrophobic barrier layer is coated on both sides of the paper and includes a water insoluble component and a water or alcohol soluble anti-curl agent. United States Patent 6,140,412 teaches a process for coating paper with an aqueous cationic polyurethane resin solution. Japanese Patent (JP)

- 2 -

11216945 discloses a process for coating paper with a composition that includes polyvinylpyrrolidone, a polyurethane resin emulsion, polyvinyl alcohol and a cationic resin.

United States Patents 4,861,644 and 5,196,262 disclose a
5 microporous material sheet which includes a matrix of linear ultrahigh molecular weight polyolefin, a large proportion of finely divided water-insoluble siliceous filler, and interconnecting pores. U.S. Patent No. 6,025,068 teaches a method of coating a microporous polyolefin substrate with a
10 coating composition which includes a binder dissolved or dispersed in a volatile aqueous liquid medium. The binder includes a film-forming organic polymer of a water-soluble poly(ethylene oxide) and a water-soluble or water-dispersible crosslinkable urethane-acrylate hybrid polymer.

15 Another coating composition for ink jet recording materials is disclosed in Japanese Patent (JP) 2001-184881. This reference discloses a coating composition that includes a nonionic or anionic polyurethane and the reaction product of a monomeric secondary amine and epichlorohydrin. Japanese
20 Patents (JP) 11268406 and (JP) 2000153667 disclose cationic polyurethanes that are useful in waterproofing coatings for ink jet printing substrates.

There remains a need for an ink jet recording medium that is durable, water-resistant and able to record sharp images
25 when an ink jet printing ink is applied thereto.

SUMMARY OF THE INVENTION

The present invention is directed to a water-resistant coating composition for an ink jet recordable substrate. The
30 coating composition has a pH of less than 7 and includes:

- (a) an aqueous polyurethane dispersion; and
- (b) an aqueous solution of a cationic nitrogen-containing polymeric dye fixative compound.

- 3 -

The present invention is also directed to a method of coating an ink jet recordable substrate in which the above-defined coating composition is applied to the substrate.

5 The present invention is further directed to an ink jet recordable substrate wherein at least one side of the substrate has a coating layer of the above-described coating composition.

DETAILED DESCRIPTION OF THE INVENTION

10 Unless otherwise indicated, all numbers or expressions referring to quantities of ingredients, reaction conditions, etc. used herein are to be understood as modified in all instances by the term "about."

Unless otherwise indicated, all references to
15 (meth)acrylic, (meth)acrylate and (meth)acrylamide monomers is meant to include both the methacrylic and acrylic species.

Various numerical ranges are disclosed in this patent application. Because these ranges are continuous, they include every value between the minimum and maximum values.

20 Unless expressly indicated otherwise, the various numerical ranges specified in this application are approximations.

The coating composition of the present invention includes an aqueous polyurethane dispersion and an aqueous solution of a cationic nitrogen-containing polymeric dye fixative
25 compound.

Suitable aqueous polyurethane dispersions for use in the present invention include any known water-dispersible nonionic polyurethanes, anionic polyurethanes, cationic polyurethanes, and mixtures thereof.

30 The mixing of an anionic polymer and a cationic polymer typically results in a polysalt which is often insoluble in water and other solvents. In the present invention, it has been surprisingly found that the addition of an aqueous solution of a cationic nitrogen-containing polymer to an
35 aqueous anionic polyurethane dispersion results in a stable

- 4 -

dispersion which is useful as a coating composition for an ink jet recordable substrate. However, a reversal in the order of addition such that the anionic polyurethane dispersion is added to the aqueous solution of a cationic nitrogen-
5 containing polymer, results in the formation and precipitation of a polysalt from the aqueous solution.

An aqueous dispersion of an anionic polyurethane resin for use in the invention comprises particles of an anionic polyurethane polymer dispersed in an aqueous medium. The
10 polyurethane polymer has at least one pendent acid group which may be neutralized in the presence of a base to form anionic group(s), which stabilize the dispersion.

The anionic polyurethane for use in the invention may be prepared by a method known in the art. For example, the
15 reaction of (i) a polyisocyanate, (ii) a polyol, (iii) a compound having an acid group, and optionally (iv) a chain-extending compound such as a polyamine or hydrazine, produces a suitable anionic polyurethane. As used herein and the claims, "polyisocyanate" refers to a compound having more than
20 one isocyanate group. Examples of suitable polyisocyanates for use in the present invention include diisocyanates such as toluene diisocyanate, hexamethylene diisocyanate, isophorone diisocyanate and dicyclohexyl methane diisocyanate; three or more functional isocyanates which may be the reaction products
25 of diisocyanates with polyols such as trimethylol propane, glycerol and pentaerythritol. Suitable polyisocyanates for use in the invention are commercially available from Bayer Corporation under the tradename Desmodur.

As used herein and the claims, "polyol" refers to a
30 compound with more than one hydroxyl group. Examples of suitable polyols are simple polyols such as those used to prepare polyisocyanate, polyester polyols and polyether polyols.

The anionic polyurethane for use in the present invention
35 may include an acid group such as a carboxylic acid or

- 5 -

sulfonic acid group and two groups, which can react with either a polyisocyanate or a polyol. An example of a group, which may react with a polyol, is an isocyanate group. Examples of groups which may react with a polyisocyanate include hydroxyl groups and amine groups. An example of a compound having two hydroxyl groups and an acid group is dimethylol proprionic acid. An example of a polyamine includes ethylene diamine, isophorone diamine or diethylene triamine.

The anionic polyurethane dispersion for use in the invention is dispersed using a base which ionizes the acidic group(s) on the polymer and stabilizes the dispersion. The base may include any known inorganic base, ammonia or an amine.

The (i) polyisocyanate, (ii) the compound having an acid group, and (iii) the polyol may be reacted in the presence of an organic solvent to form an isocyanate-terminated prepolymer. Suitable organic solvents include n-methyl pyrrolidone, tetrahydrofuran or a glycol ether. The isocyanate-terminated prepolymer may be dispersed in water in the presence of a base, and then chain extended by adding the polyamine. In an embodiment, the prepolymer is chain extended in an organic solvent solution and then the polyurethane polymer is dispersed in water in the presence of the base.

Suitable anionic polyurethanes for use in the present invention include anionic polyurethanes based on aromatic polyether polyurethanes, aliphatic polyether polyurethanes, aromatic polyester polyurethanes, aliphatic polyester polyurethanes, aromatic polycaprolactam polyurethanes, and/or aliphatic polycaprolactam polyurethanes. An anionic polyurethane dispersion for use in the present invention is commercially available from Crompton Corporation under the tradename WitcoBond®.

The aqueous anionic polyurethane dispersion of the coating composition contains up to 70 wt.%, or up to 65 wt.%, or up to 60 wt.%, or up to 50 wt.% of the anionic

- 6 -

polyurethane. The aqueous anionic polyurethane dispersion includes at least 1 wt.%, or at least 5 wt.%, or at least 10 wt.%, or at least 20 wt.% of the anionic polyurethane. The amount of anionic polyurethane in the aqueous anionic polyurethane dispersion is not critical. In general, the amount should not be so high as to cause the dispersion itself or the mixture with the nitrogen-containing polymer to be unstable, or so low that the coating composition does not provide sufficient water and rub resistance or that the dispersion itself becomes unstable. The anionic polyurethane may be present in the aqueous anionic polyurethane dispersion in any range of values inclusive of those stated above.

The cationic polyurethane dispersion for use in the present invention may include a known water-dispersible cationic polyurethane. Suitable cationic polyurethanes are available commercially from Crompton Corporation under the tradename Witcobond, for example, Witcobond W-213 and W-215 formulations.

The cationic polyurethane may be prepared by a method known in the art. United States Patent 3,470,310 discloses the preparation of a water dispersion of a polyurethane which contains salt-type groups bonded into the polyurethane. United States Patent 3,873,484 discloses an aqueous dispersion of a polyurethane prepared from quaternized polyurethane prepolymer prepared by reacting an alkoxylated diol, an N-alkyl dialkanolamine, an organic diisocyanate and quaternizing with a dialkyl sulfate quaternizing agent. United States Patent 6,221,954 teaches a method for making a polyurethane prepolymer in which a N-monoalkanol tertiary amine is reacted with an alkylene oxide in the presence of a strong acid to form a polyol salt, which is further reacted with an excess amount of an organic polyisocyanate and chain extended with an active hydrogen-containing compound. These references are herein incorporated by reference.

- 7 -

The aqueous cationic polyurethane dispersion for use in the present invention contains up to 70 wt.%, or up to 65 wt.%, or up to 60 wt.%, or up to 50 wt.% of the cationic polyurethane. The aqueous cationic polyurethane dispersion includes at least 1 wt.%, or at least 5 wt.%, or at least 10 wt.%, or at least 20 wt.% of the cationic polyurethane. The amount of cationic polyurethane in the aqueous cationic polyurethane dispersion is not critical. In general, the amount should not be so high as to cause the dispersion itself or the mixture with the nitrogen-containing polymer to be unstable, or so low that the coating composition does not provide sufficient water and rub resistance or that the dispersion itself becomes unstable. The cationic polyurethane may be present in the aqueous cationic polyurethane dispersion in any range of values inclusive of those stated above.

The nonionic polyurethane dispersion for use in the present invention may include a known water-dispersible nonionic polyurethane. Suitable cationic polyurethanes are available commercially from Crompton Corporation under the tradename Witcobond, for example, Witcobond W-230 formulation.

The nonionic polyurethane may be prepared by a method known in the art. For example, Szycher (i.e., "Szycher's Book of Polyurethanes" by Michael Szycher, CRC Press, New York, NY, 1999, pages 14-10 through 14-15) describes the preparation of water dispersions of polyurethanes, which contain hydrophilic polyether-type groups either branching off or terminating on the main polyurethane chains. Polyethylene oxide units (having a molecular weight (MW) of from 200 to 4,000) are typically used as dispersing sites. Nonionic polyurethanes may be prepared by the use of diols or diisocyanate comonomers bearing pendant polyethylene oxide chains.

The aqueous nonionic polyurethane dispersion for use in the present invention contains up to 70 wt.%, or up to 65 wt.%, or up to 60 wt.%, or up to 50 wt.% of the nonionic polyurethane. The aqueous nonionic polyurethane dispersion

- 8 -

includes at least 1 wt.%, or at least 5 wt.%, or at least 10 wt.%, or at least 20 wt.% of the nonionic polyurethane. The amount of nonionic polyurethane in the aqueous nonionic polyurethane dispersion is not critical. In general, the amount should not be so high as to cause the dispersion itself or the mixture with the nitrogen-containing polymer to be unstable, or so low that the coating composition does not provide sufficient water and rub resistance or that the dispersion itself becomes unstable. The nonionic polyurethane may be present in the aqueous nonionic polyurethane dispersion in any range of values inclusive of those stated above.

The aqueous solution of a cationic nitrogen-containing polymer for use as a dye fixative in the coating composition of the present invention, has a pH of less than 7, or less than 6, or less than 5. A pH value within this range allows for at least a portion of the nitrogen atoms to carry at least a portion of a cationic charge. The resulting coating composition will have a pH of less than 7, or less than 6, or less than 5.

As used herein and in the claims, "aqueous solution" means that the cationic nitrogen-containing polymer is soluble in a liquid medium such as water.

A dye fixative is generally used to fix dyes to a substrate to preclude the dyes from bleeding or migrating out of the substrate when the substrate is contacted with water.

A known cationic nitrogen-containing polymer in which at least a portion of the nitrogen atoms carry at least a portion of a cationic charge within the above-mentioned pH range of the coating composition, may be used in the present coating composition as a dye fixative. Suitable cationic nitrogen-containing polymers include cationic polymers having one or more monomer residues derived from one or more of the following nitrogen-containing monomers:

- 9 -

- 5 where R^1 represents independently for each occurrence in each structure, H or C_1 to C_3 aliphatic; R^2 represents independently for each structure a divalent linking group selected from C_2 to C_{20} aliphatic hydrocarbon, polyethylene glycol and polypropylene glycol; R^3 represents independently for each
- 10 occurrence in each structure H, C_1 to C_{22} aliphatic hydrocarbon or a residue from the reaction of the nitrogen with epichlorohydrin; Z is selected from -O- or - NR^4 -, where R^4 is H or CH_3 ; and X is a halide or methylsulfate.

Examples of nitrogen-containing monomers or resulting

15 monomer residues for use in the present invention include

- 10 -

dimethyl aminoethyl (meth)acrylate, (meth)acryloyloxyethyl
trimethyl ammonium halides, (meth)acryloyloxyethyl trimethyl
ammonium methylsulfate, dimethyl aminopropyl (meth)acrylamide,
(meth)acrylamidopropyl trimethyl ammonium halides, aminoalkyl
5 (meth)acrylamides where the amine is reacted with
epichlorohydrin, (meth)acrylamidopropyl trimethyl ammonium
methylsulfate, diallyl amine, methyl diallyl amine, and
diallyl dimethyl ammonium halides.

The cationic nitrogen-containing polymers may contain
10 additional monomer residues. The additional monomer residues
may be obtained from any polymerizable ethylenically
unsaturated monomer that, when copolymerized with the
nitrogen-containing monomers allows the resulting polymer to
be at least partially soluble in water. As used herein and the
15 claims, "partially soluble" refers to at least 0.1 gram of the
polymer dissolving in water when ten (10) grams of the polymer
is added to one (1) liter of water and mixed for 24 hours.

Examples of monomers that may be copolymerized with the
nitrogen-containing monomers include (meth)acrylamide, n-alkyl
20 (meth)acrylamides, (meth)acrylic acid, alkyl esters of
(meth)acrylate, glycol esters of (meth)acrylic acid,
polyethylene glycol esters of (meth)acrylic acid, hydroxyalkyl
(meth)acrylates, itaconic acid, alkyl ethers of itaconic acid,
maleic acid, mono- and di-alkyl esters of maleic acid, maleic
25 anhydride, maleimide, aconitic acid, alkyl esters of aconitic
acid, allyl alcohol and alkyl ethers of allyl alcohol.

In an embodiment, the cationic nitrogen-containing
polymer is a homopolymer of a nitrogen-containing monomer, or
a copolymer of one or more nitrogen-containing monomers. In
30 another embodiment, the nitrogen-containing polymer is a
copolymer of one or more polymerizable ethylenically
unsaturated monomers and one or more nitrogen containing
monomers. When the nitrogen-containing polymer includes any of
the aforementioned additional polymerizable ethylenically
35 unsaturated comonomers, the nitrogen-containing polymer

- 11 -

includes not more than 70 mol%, or not more than 50 mol%, or not more than 25 mol%, or not more than 10 mol% of the nitrogen-containing monomer. The amount of nitrogen-containing monomer may be dependent upon the specific polyurethane used in the present coating composition. When the amount of the nitrogen-containing monomer used in the nitrogen-containing polymer is too high, an unstable mixture of the nitrogen-containing polymer and polyurethane dispersion may result. It is typically difficult to properly apply an unstable mixture to an ink recordable substrate.

When the nitrogen-containing polymer includes any of the aforementioned additional polymerizable ethylenically unsaturated comonomers, the nitrogen-containing polymer includes at least 0.1 mol%, or at least 1.0 mol%, or at least 2.5 mol%, or at least 5.0 mol% of the nitrogen-containing monomer. When the amount of nitrogen-containing monomer in the nitrogen-containing polymer is too low, the nitrogen-containing polymer may not provide adequate dye fixative properties and a recorded ink image on the coated substrate may lack water and rub fastness properties.

The nitrogen-containing monomers may be present in the nitrogen-containing polymer in any range of values inclusive of those stated above. The additional polymerizable ethylenically unsaturated monomers will be present in an amount such that the total percentage is 100 mol%.

In the present invention, the aqueous solution of the cationic nitrogen-containing polymeric dye fixative includes at least 5 wt.%, or at least 10 wt.%, or at least 15 wt.% of the nitrogen-containing polymer; and not more than 50 wt.%, or not more than 45 wt.%, or not more than 40 wt.% of the nitrogen-containing polymer. When the concentration of the nitrogen-containing polymer is too low, it is not economical for commercial applications and may be too dilute to provide optimum ratios with the polyurethane. When the concentration is too high, the solution may be too viscous to easily handle

- 12 -

in a commercial environment. Examples of cationic nitrogen-containing polymers useful in the present invention are solutions of polyamide amines reacted with epichlorohydrin, available under the trade name CinFix from Stockhausen GmbH & Co. KG, Krefeld, Germany.

The ink jet recordable substrate coating composition of the present invention includes a mixture of an aqueous solution of a cationic nitrogen-containing polymer and an aqueous polyurethane dispersion. The mixture includes from 10 wt.% to 70 wt.%, or from 20 wt.% to 60 wt.%, or from 30 wt.% to 50 wt.% of an aqueous polyurethane dispersion. The mixture will also include from 30 wt.% to 90 wt.%, or from 40 wt.% to 80 wt.%, or from 50 wt.% to 70 wt.% of an aqueous solution of the cationic nitrogen-containing polymer. The weight percentages are based on the total weight of the ink jet recordable substrate coating composition.

In an embodiment of the present invention, water is added to the mixture of the cationic nitrogen-containing polymer and the polyurethane. When water is added to the mixture, the resulting ink jet recordable substrate coating composition has a total resin solids of from 1 wt.% to 35 wt.%, or from 1 wt.% to 20 wt.%, or from 1 wt.% to 10 wt.% based on the total weight of the ink jet recordable substrate coating composition. When the total resin solids is too high, the viscosity of the coating composition may be such that poor penetration of the coating composition results. When the total resin solids is too low, the viscosity of the coating composition may be such that poor coating to the substrate results. In an embodiment, the viscosity of the coating composition of the present invention is less than 500 cps, or less than 400 cps; and at least 10 cps, or at least 25 cps when measured using a Brookfield viscometer (RVT, spindle no. 1, 50 rpm at 25°C). A viscosity within the aforementioned ranges provides for the coating composition to wet the

substrate while maintaining a degree of porosity in the final coated substrate.

In an embodiment, the coating composition of the present invention includes a co-solvent. A co-solvent known in the art may be used. Suitable co-solvents include lower alkyl alcohols,

n-methylpyrrolidone, Dowanol PM, toluene, and glycol ethers.

The coating composition of the present invention may also include other additives typically known in the art. Such additives include surfactants, such as nonionic, cationic, anionic, amphoteric and zwitterionic surfactants; rheology modifiers, such as polyvinyl alcohols, polyvinyl pyrrolidones, polyethylene oxides, polyacrylamides, natural and synthetic gums; biocides, such as a blend of 5-chloro-2-methyl-4-isothiazoline-3-one and 2-methyl-4-isothiazolin-3-one available commercially by the trade name Kathon, from Rohm and Haas Co., 2-hydroxypropylmethane thiosulfonate, and dithiocarbamates; and coupling agents, such as titanium, silane-type, trisodium pyrophosphate.

The pH of the coating composition of the present invention is less than 7, or less than 6, or less than 5. When the pH is outside of these ranges, the cationic polymeric dye fixative compound may not carry a sufficient cationic charge to perform its intended function. Further, on certain substrates the wetting action of the coating composition may be improved when the pH is within the aforementioned ranges. In an embodiment, for commercial applications, the coating composition has pH greater than 2.

The present invention is also directed to a method of preparing the ink jet recordable substrate coating composition. The present method includes the step of adding the aqueous solution of a cationic nitrogen-containing polymer into an aqueous polyurethane dispersion. Sufficient mixing is maintained during the addition to ensure that a homogeneous mixture results. It has been observed that when the aqueous

anionic polyurethane dispersion is added to the aqueous solution of a cationic nitrogen-containing polymer, coagulation occurs and a homogeneous mixture is not obtained.

The present invention is further directed to a method of coating an ink jet recordable substrate. The method includes the steps of:

(a) providing an ink jet recordable substrate having a top surface and a bottom surface;

(b) providing the coating composition described above; and

(c) applying the coating composition to at least one surface of the ink jet recordable substrate.

Any ink jet recordable substrate may be used in the present invention. The ink jet recordable substrate has a porosity of at least 35%, or from 35% to 80%, by volume of the substrate. The ink jet recordable substrate for use in the present invention may be any cellulosic-based paper. United States 4,861,644 and 5,196,262, both of which are herein incorporated by reference, describe suitable microporous substrates for use in the present invention.

In an embodiment, the ink jet recordable substrate is a microporous substrate. An example of a suitable microporous substrate includes an ink jet recordable substrate having a top surface and a bottom and which includes:

(a) a matrix comprising a polyolefin;

(b) a particulate siliceous filler distributed throughout the matrix; and

(c) a network of interconnecting pores communicating throughout the microporous substrate, wherein the pores constitute at least 35 percent by volume of the microporous substrate.

Any polyolefin known in the art such as polyethylene or polypropylene may be used in the microporous substrate. In an embodiment, the polyethylene is a linear high molecular weight polyethylene having an intrinsic viscosity of at least 10

- 15 -

deciliters/gram and the polypropylene is a linear high molecular weight polypropylene having an intrinsic viscosity of at least 5 deciliters/gram.

As recorded herein and in the claims, intrinsic viscosity is determined by extrapolating to zero concentration the reduced viscosities or the inherent viscosities of several dilute solutions of the polyolefin wherein the solvent is distilled decahydronaphthalene to which 0.2 percent by weight, 3,5-di-tert-butyl-4-hydroxyhydrocinnamic acid, neopentametrayl ester [CAS Registry No. 6683-19-8] has been added. The reduced viscosities or the inherent viscosities of the polyolefin are ascertained from relative viscosities obtained at 135°C using an Ubbelohde No. 1 viscometer.

On a coating-free, printing ink free, impregnant-free, and pre-bonding basis, pores constitute at least 35 percent by volume of the microporous substrate. In some instances, the pores constitute at least about 60 percent by volume of the microporous substrate, or from 35 percent to about 80 percent, or from 60 percent to 75 percent by volume of the microporous substrate.

The siliceous particles may be in the form of ultimate particles, aggregates of ultimate particles, or a combination of both. As used herein and in the claims, the term "ultimate particles" refers to small discrete particles of colloidal polymerized silicic acid units which make up amorphous silica. The term "aggregate" as used herein and in the claims, refers to a structure wherein ultimate particles are condensed to produce an open but continuous structure of chains or a solid structure of interconnecting pores.

In an embodiment, the siliceous particles are finely-divided. As used herein and in the claims, "finely-divided" refers to a maximum retention of 0.01% by weight on a 40 mesh sieve screen.

In a further embodiment, the siliceous particles are substantially insoluble. As used herein and in the claims,

- 16 -

the term "substantially insoluble" refers to amorphous silica exhibiting a reproducible equilibrium solubility in water which may range from 70 ppm to greater than 150 ppm in water at a temperature of 25°C. It is believed that variations in solubility are due to differences in particle size, state of internal hydration and the presence of trace impurities in the silica or absorbed on its surface. The solubility of the silica may also be dependent on the pH of the water. As pH increases from neutrality (i.e., pH of 7) to alkalinity (i.e., pH greater than 9), the solubility of silica may increase. (See "The Chemistry of Silica", R.K. Iler, Wiley-Interscience, NY (1979), pp. 40-58.)

In the present invention, at least 90 percent by weight of the siliceous particles used in preparing the microporous substrate have particle sizes in the range of from 5 to 40 micrometers. The particle size is determined by use of a Model TaII Coulter Multisizer Particle Size Analyzer (Coulter Electronics, Inc.) wherein, prior to analysis by the Coulter Analyzer, the filler is stirred for 10 minutes in Isoton II electrolyte solution (Curtin Matheson Scientific, Inc.) using a four-blade, 4.445 centimeter diameter propeller stirrer. In an embodiment, at least 90 percent by weight of the siliceous particles have particle sizes in the range of from 10 to 30 micrometers. It is expected that the sizes of filler agglomerates may be reduced during processing of the ingredients to prepare the microporous substrate.

Suitable siliceous particles include, but are not limited to particles of silica, mica, montmorillonite, kaolinite, asbestos, talc, diatomaceous earth, vermiculite, natural and synthetic zeolites, cement, calcium silicate, aluminum silicate, sodium aluminum silicate, aluminum polysilicate, alumina silica gels, and glass particles. Silica and the clays are commonly used siliceous particles. In an embodiment, precipitated silica, silica gel, or fumed silica is used.

- 17 -

In an embodiment, the siliceous particles are coated prior to incorporation in the microporous substrate. A method known in the art may be used to coat the particles. The selection of the method of coating the siliceous particles is not critical. For example, the coating ingredients may be added to an aqueous slurry of pre-washed silica filter cake under sufficient stirring to allow for complete mixing of the ingredients, followed by drying, using conventional techniques known in the art.

10 The coating may include the aforementioned aqueous polyurethane dispersions, and/or the aforementioned cationic nitrogen-containing polymeric compounds.

United States Patent Applications having serial numbers 09/636,711; 09/636,312; 09/636,310; 09/636,308; 09/636,311 and 15 10/041,114; disclose suitable coating compositions and methods of coating silica particles which may be used in the present invention, and which by reference are incorporated herein.

The particulate siliceous filler constitutes from 50 to 90 percent by weight of the microporous substrate. In an embodiment, the filler constitutes from 50 to 85 percent, or 20 from 60 to 80 percent by weight of the microporous substrate.

In addition to the siliceous particles, substantially water-insoluble non-siliceous filler particles may also be used in the microporous substrate. Examples of such optional 25 non-siliceous filler particles include particles of titanium oxide, iron oxide, copper oxide, zinc oxide, antimony oxide, zirconia, magnesia, alumina, molybdenum disulfide, zinc sulfide, barium sulfate, strontium sulfate, calcium carbonate, magnesium carbonate, magnesium hydroxide, and finely divided 30 substantially water-insoluble flame retardant filler particles such as particles of ethylenebis(tetra-bromophthalimide), octabromodiphenyl oxide, decabromodiphenyl oxide, and ethylenebisdibromonorbornane dicarboximide.

In an embodiment of the invention, the substrate is 35 highly porous. The term "highly porous" refers to a substrate

- 18 -

having a porosity of not more than 20,000, or not more than 10,000 and in many cases not more than 7,500 seconds/100cc air. The porosity is typically at least 50 seconds/100cc air. These porosity values are determined in accordance with the method described in ASTM D726, with the following exceptions relative to Section 8 of the ASTM. In the present invention, the sheet samples are tested without conditioning in accordance with ASTM D685, and only three (3) specimens for a given sample type are tested for a total of six (6) measurements (three measurements per two surfaces) for a given specimen type rather than a minimum of ten specimens for a given samples as stated in ASTM D726. The lower the value in seconds/cc air, the more porous is the substrate. Highly porous substrates may be produced by various methods known in the art, such as thermally treating a substrate, orienting, compositionally by increasing the filler content, microvoiding films, or etching. Examples of highly porous substrates include thermally treated microporous materials such as Teslin TS-1000 which is commercially available from PPG Industries, Inc., Pittsburgh, PA.

The coated microporous substrate has a thickness of at least 0.1 mils, or from 0.5 to 100 mils, or from 1 to 50 mils, and in some cases from 4 to 14 mils. When the coated microporous substrate has a thickness which exceeds the aforementioned ranges, it may not feed properly through an ink jet printer. When the coated microporous substrate is below the stated ranges, it may not have sufficient strength for its intended use.

Any method known in the art may be used to apply the coating composition of the present invention to the ink jet recordable substrate such as flexography, spraying, air knife coating, curtain coating, dipping, rod coating, blade coating, gravure, reverse roll, roller application, imbibing, size press, printing, brushing, drawing, slot-die coating, and extrusion.

- 19 -

Following application of the coating composition to said substrate, the solvent is removed from the applied coating by any conventional drying technique. In an embodiment, the coating is dried by exposing the coated substrate to a
5 temperature ranging from ambient to 350°F.

The coating composition is applied at least one time to at least one surface of the substrate. When the coating composition is applied more than one time, the applied coating is usually but not necessarily dried, either partially or
10 totally, between coating applications.

When the coating composition is applied to a microporous substrate, the coating composition will often penetrate into the substrate. Penetration of the coating layer into the microporous substrate improves the ink jet print quality on
15 the coated substrate. Typically, the coating layer penetrates into at least the first one (1) micron of the surface of the microporous substrate. In some instances, the coating layer penetrates into at least the first ten (10) microns, or at least the first twenty (20) microns or at least the first
20 thirty (30) microns of the microporous substrate.

In an embodiment of the present invention, the coating composition is applied to the substrate using an air knife coating technique where the excess coating is 'blown off' by a powerful jet from the air knife. In another embodiment, a
25 reverse roll coating method is used. In this procedure, the coating composition is measured onto an applicator roller by precision setting of the gap between an upper metering roller and the application roller below it. The coating is wiped-off the application roller by the substrate as it passes around
30 the support roller at the bottom.

In another embodiment of the present invention, gravure coating is used to apply the coating composition. In the gravure coating method, an engraved roller runs in a coating bath, which fills the engraved dots or lines of the roller
35 with the coating composition. Any excess coating on the roller

- 20 -

is wiped off by a doctor blade and the coating is deposited onto the substrate as it passes between the engraved roller and a pressure roller. Reverse gravure coating methods may be used. In this method, the coating composition is metered by the engraving on a roller before being wiped off as in a conventional reverse roll coating process.

In a further embodiment a metering rod may be used to apply the coating composition. When a metering rod is used, an excess of the coating is deposited onto the substrate as it passes over a bath roller. The wire-wound metering rod, sometimes known as a Meyer Bar, allows the desired quantity of the coating to remain on the substrate. The quantity is determined by the diameter of the wire used on the rod.

The amount of the substantially dry coating applied to the substrate, or "coat weight", is measured as coating weight per coated area. The coat weight may vary widely, but in most instances will be at least 0.001 g/m^2 , or at least 0.01 g/m^2 , and in some cases at least 0.1 g/m^2 . The coat weight is not more than 50 g/m^2 , or not more than 40 g/m^2 , and in some cases not more than 35 g/m^2 . The coat weight may vary between any of the stated amounts.

The present invention is also directed to a coated microporous substrate. The coated microporous substrate includes the microporous substrate having at least one coated surface as described above. The surface is coated with the aforementioned coating composition which includes a cationic polymeric nitrogen containing dye fixative compound and one or more polyurethanes as described above. The substantially dried coating layer includes the polyurethane at from 10 to 70 percent, or from 20 to 60 percent, and in some cases from 30 to 55 percent by weight of the coating layer and the nitrogen-containing polymer at from 30 to 90 percent, or from 40 to 80 percent, and in some cases from 45 to 70 percent by weight of the coating layer. The amount of each component in the

- 21 -

substantially dried coating layer is determined by the amount of each used to prepare the coating composition.

As used herein and in the claims, "substantially dry" is used to refer to the coating layer that feels dry to touch.

5 The present invention is more particularly described in the following examples, which are intended to be illustrative only, since numerous modifications and variations therein will be apparent to those skilled in the art. Unless otherwise specified, all parts and percentages are by weight and all
10 references to water are meant to be deionized water.

EXAMPLES

Example 1

A coating composition of the present invention was
15 prepared by diluting in a stainless steel mix tank under high speed mixing with an overhead mixer, a 61.5% solids by weight anionic polyurethane dispersion sold under the trade name WitcoBond® 234 available from Crompton Corporation, Greenwich, Connecticut, to 9.22% solids by weight. In a separate feed
20 tank a 55% solids by weight solution of a polyamide amine reacted with epichlorohydrin sold under the trade name CinFix NF by Stockhausen GmbH & Co. KG, Krefeld, Germany, was diluted to 5.78% solids by weight, and subsequently added to the diluted anionic polyurethane dispersion, and the mixture was
25 mixed for 15 minutes. The pH was adjusted with glacial acetic acid to 5.0 ± 0.5 . The total resin solids of the mixture was 7.5% and the viscosity of the mixture was 46 cps as measured using a Brookfield viscometer, RVT, spindle no. 1, at 50 rpm and 25°C.

30

Examples 2-4

Coating compositions were prepared as described in Example 1 and applied to microporous substrates sold under the tradename Teslin by PPG Industries, Pittsburgh, PA. A sheet
35 of 8.5" x 11", 10 mil thick, Teslin® was placed on a 15" x 20"

- 22 -

x 20 mil backing sheet. A metering bar was placed 1 - 2 inches above the Teslin sheet, parallel to the top edge. A 10 - 20 ml quantity of coating was drawn into a disposable plastic syringe. The coating was deposited as a bead strip (approximately 1/8 inches wide) directly next to and touching the metering bar. The bar was drawn completely across the sheet of Teslin, attempting a continuous/constant rate. The resultant wet sheet was placed in a forced air oven, secured and dried at 95°C for 2 minutes. The dried sheet was removed from the oven and the same coating procedure was repeated on the opposite side of the sheet. The sheet was then printed and tested. Table 1 shows characteristics of the printed sheets. The coating compositions were applied with an approximate coat weight of 0.73 g/m² (total front and back). As used herein and the claims, "coat weight" refers to the consumption rate of coating (as dry solids) per unit area. For example, the coat weight of "X" grams of coating (as dry solids) consumed in coating "Y" square meters of Teslin, is "X divided by Y" grams per square meter.

TABLE 1

	Substrate	Polyurethane	Meyer Bar
Example 2	Teslin SP1000	WitcoBond UCK 051	#6 Rod
Example 3	Teslin TS1000	WitcoBond UCK 051	#9 Rod
Example 4	Teslin TS1000	WitcoBond 234	#9 Rod

Examples 2-4 were printed with an ink jet printer, Model HP960 by Hewlett Packard Company, Palo Alto, California and soaked overnight in water at ambient temperature. Based on visual inspection, it appeared that the recorded images remained intact, i.e., the ink did not bleed and the optical density of the image was not significantly decreased.

Examples 5-8

A coating composition was prepared as described in Example 1 and applied to Teslin microporous substrates. Two

- 23 -

substrates (Examples 5 and 7) were coated using a metering bar as described in Example 2. For coating compositions having a total resin solids of 7.5%, the viscosity was 46 cps; and for 10.0% solids, the viscosity was 63 cps. The viscosity values were measured using a Brookfield viscometer, RVT, spindle no. 1, at 50 rpm and 25°C.

Two substrates (Examples 6 and 8) were coated using a flexographic or gravure coating method to apply the coating. In this coating method, a line consisting of two coating stations, each with a forced air drying oven was used. Each coating station consists of a coating feed chamber, anilox roll and rubber application roll. The coating feed chamber was supplied from a coating holding tank and pump. Both sides of the Teslin sheet were coated. The apparatus was fitted with a 7 BCM (billion cubic microns) anilox roll, line speed was 180 fpm, oven temperature was 105°C (220°F) and 8 passes per roll were made, which translates into four passes per surface. The coating compositions were applied with an approximate coat weight of 0.73 g/m² (total front and back).

Table 2 shows the characteristics of the sheets produced.

TABLE 2

	Substrate	Polyurethane	Coating Method	Total Resin Solids %
Example 5	Teslin TS1000	WitcoBond 234	Meyer #9 Rod	7.5
Example 6	Teslin TS1000	WitcoBond 234	7 BCM Anilox (5 BPS*)	7.5
Example 7	Teslin TS1000	WitcoBond 234	Meyer #9 Rod	10.0
Example 8	Teslin TS1000	WitcoBond 234	7 BCM Anilox (4 BPS*)	10.0

*BPS = Bumps Per Surface

The resultant coated sheets were printed with a test print pattern on a Model HP970 (Hewlett Packard Company) ink jet printer. Color bars from the test print pattern were measured for optical density by submerging in deionized water at ambient temperature for a period of 15 minutes, removing from the water and allowing to air dry for one hour and

- 24 -

measuring each color for optical density. The optical density of cyan(C), magenta (M), yellow, black (K) and composite black (CMY) were measured using a Model RD922, MacBeth ANSWER II densitometer, manufactured by Kolimorgen Instrument Corporation, before and after water soak. The results are shown in Table 3.

TABLE 3

	Initial Optical Density ¹					Optical Density @ 15 Minute Water Soak				
	CMY	C	M	Y	K	CMY	C	M	Y	K
Example 5	1.34	1.04	1.08	0.76	1.37	1.33	1.07	1.04	0.81	1.42

10 Example 9

A 9.22% solids by weight solution of WitcoBond 234 was applied to a Teslin TS1000 substrate using a metering bar as described in Examples 2-4. Immediately thereafter, a 5.78% solids by weight solution of CinFix NF was similarly applied to the substrate. The coated Teslin TS1000 was then dried at 95°C for 2 minutes. The dried sheet was removed from the oven and the same coating procedure was repeated on the opposite side of the sheet. A test print pattern was printed on the coated Teslin using an HP970 Inkjet Printer as described in Examples 5-8. Based on visual inspection, the printed image demonstrated excessive ink bleeding and poor drying properties.

Example 10

25 A 5.78% solids by weight solution of CinFix NF was applied to a Teslin TS1000 substrate as described in Examples 2-4. Immediately thereafter, a 9.22% solids by weight solution of WitcoBond 234 was similarly applied to the substrate. The coated Teslin TS1000 was then dried at 95°C for 30 2 minutes. The dried sheet was removed from the oven and the

- 25 -

same coating procedure was repeated on the opposite side of the sheet. A test print pattern was printed on the coated Teslin using an HP970 Inkjet Printer as described in Examples 5-8. Based on visual inspection, the printed image demonstrated excessive ink bleeding and poor drying properties.

Example 11

A 5.78% solids by weight solution of CinFix NF was applied to a Teslin TS1000 substrate as described in Examples 2-4. The coated Teslin TS1000 was then dried at 95°C for 2 minutes. The dried sheet was removed from the oven and the same coating procedure was repeated on the opposite side of the sheet. A test print pattern was printed on the coated Teslin using an HP970 Inkjet Printer as described in Examples 5-8. Based on visual inspection, the printed image was acceptable, however, the printed substrate demonstrated poor water resistance.

Example 12

A 9.22% solids by weight solution of WitcoBond 234 was applied to a Teslin TS1000 substrate as described in Examples 2-4. The coated Teslin TS1000 was then dried at 95°C for 2 minutes. The dried sheet was removed from the oven and the same coating procedure was repeated on the opposite side of the sheet. A test print pattern was printed on the coated Teslin using an HP970 Inkjet Printer as described in Examples 5-8. Based on visual inspection, the printed image demonstrated unacceptable print quality.

Example 13

A coating composition was prepared by diluting in a stainless steel mix tank under high speed mixing with an overhead mixer, a 61.5% solids by weight anionic polyurethane dispersion sold under the trade name WitcoBond® 234 available

- 26 -

from Crompton Corporation, Greenwich, Connecticut, to 9.22% solids by weight. In a separate feed tank a 55% solids by weight solution of a polyamide amine reacted with epichlorohydrin sold under the trade name CinFix NF by Stockhausen GmbH & Co. KG, Krefeld, Germany, was diluted to 5.78% solids by weight. The WitcoBond 234 dispersion was added to the diluted CinFix NF solution. The resulting suspension demonstrated an unacceptably heavy precipitate which was a polysalt of the CinFix NF and WitcoBond 234.

Examples 14-16

Coating compositions were prepared as in Example 1 and were applied to silk fabric (0.10lb/sq yd, 5mil gauge), cotton fabric (0.34lb/sq yd, 13.6mil gauge) and a polypropylene/cellulose nonwoven substrate (0.14lb/sq yd, 9.5mil gauge). For each material coated, a sheet (8.5" x 11") was fixed to a 15" x 20" x 20 mil backing sheet. A metering bar was placed 1 - 2 inches above the top of the sheet, parallel to the top edge. A 10 - 20 ml quantity of coating was drawn into a disposable plastic syringe. The coating was deposited as a bead strip (approximately 1/8 inches wide) directly next to and touching the metering bar. The bar was drawn completely across the sheet at a continuous/constant rate. The resultant wet sheet was placed in a forced air oven, secured and dried at 95°C for 2 minutes. The dried sheet was removed from the oven and the same coating procedure was repeated on the opposite side of the sheet. The sheet was then taped to a transparency sheet to provide rigidity and was then ready to be printed and tested. The coating compositions were applied with an approximate coat weight of 0.73 g/m² (total front and back). Coat weight was determined as previously described in Examples 2-4.

Examples 14 - 16 were printed with an ink jet printer, Model HP970 by Hewlett Packard Company, Palo Alto, California and compared to the same substrates without coating. After

- 27 -

printing, each sheet was removed from the rigid transparency sheet. Coated and uncoated printed sheet types were soaked in water at ambient temperature for 5 days. Optical density was measured after 5 days of soaking. The optical density of cyan (C), magenta (M), yellow (Y), black (K) and composite black (CMY), were measured using a Model RD922, MacBeth ANSWER II Densitometer, manufactured by Kolimorgen Instrument Corporation, before and after water soak.

The recorded images for the coated substrates remained intact after 15 minutes, i.e., the ink did not bleed or the optical density of the image was not significantly decreased for each sample. The uncoated sheets bled immediately, completely washing away the printed image within the 15 minute soak time. The printed image on each of the coated substrate did experience ink bleed after 5 day water soak exposure, as seen by the optical density values. The resultant printed images were faded but had good line sharpness and legible text.

Example 17

A coating composition designated herein as "01" was prepared as follows. In a mixing vessel under high speed mixing with an overhead mixer, a 61.5% solids by weight anionic polyurethane dispersion sold under the trade name

- 28 -

Witcobond W-234 available from Crompton Corporation, Greenwich, Connecticut, was diluted with deionized water to a 10.0% solids by weight dispersion. In a separate vessel, a 55% solids by weight solution of a polyamide amine reacted with epichlorohydrin sold under the trade name CinFix NF available from Stockhausen GmbH & Co. KG, Krefeld, Germany, was diluted with deionized water to a 10.0% solids by weight solution, and was subsequently added to the diluted anionic polyurethane dispersion. The mixture was mixed for fifteen minutes following completion of the addition. The resulting mixture contained 40 parts by weight of solids of CinFix NF and 60 parts by weight of solids of Witcobond W-234.

A second coating was prepared as above-described with the exception that CinFix NF was replaced on an equivalent dry solids basis with CinFix RDF. This second coating composition is referred to herein as 01/RDF. CinFix RDF is a water solution of poly(diallyl dimethyl ammonium chloride) at 31% solids commercially available from Stockhausen GmbH & Co. KG, Krefeld, Germany. The CinFix RDF was diluted to 10.0% solids by weight prior to addition to the Witcobond W-234.

A third coating was prepared as above-described for the "01" composition with the exception that CinFix NF was replaced on an equivalent dry solids basis with diallyldimethylammonium chloride. This third coating composition is referred to herein as "01/DADMAC". Diallyldimethyl ammonium chloride is commercially available from Aldrich Chemical Company of Milwaukee, WI, as a 65% solution in water. It was diluted to 10.0% solids by weight prior to addition to the Witcobond W-234.

A fourth coating was prepared as above-described for the "01" composition with the exception that CinFix NF was replaced on an equivalent dry solids basis with the reaction product of equimolar amounts of diethyl amine and epichlorohydrin at 30% solids in water. This fourth coating composition is referred to herein as "01/DEA-EPI". The

- 29 -

reaction product was not completely miscible with water in the 30/70 parts by weight mix necessary for 30% solids and therefore, was acidified to a pH of 5 with acetic acid to render it soluble in water for use in the coating. It was
 5 diluted to 10.0% solids prior to addition to the Witcobond W-234.

Sheets of Teslin® TS1000 and SP1000 were coated on both sides with each of the above-mentioned coatings using a #9 rod. The coating was applied to the front surface, dried for
 10 a period of two minutes at a temperature of 95°C, and then applied to the back surface and dried for two minutes at 95°C. The finished sheets were then printed with a pattern on a Hewlett-Packard 960C printer at "HP Premium Photo Paper - Glossy" setting. The color density of the printed color bar
 15 section of the pattern was measured using an X-Rite Model 418 Densitometer, calibrated on a white tile standard. The printed color bar section was cut out of each sheet and immersed in a beaker of de-ionized water overnight (i.e., 14 hours). The sections were then removed from the water baths
 20 and allowed to air dry for a period of four hours. The color density after soak was then measured.

The results are shown in the following table:

Coating	Substrate	Soak	CMY	C-100	M-100	Y-100	K-100
"01"	TS1000	No	1.31	1.23	1.24	0.93	1.31

- 30 -

The "01" coating on either substrate exhibited acceptable color density and water resistance and there was no visual evidence of color bleed. Based on visual inspection, the printed images were crisp and clear. The "01/RDF" coating also demonstrated acceptable color density and water resistance, showing no visual bleed. However, based on visual inspection there was a slight "feathering" or blurring of the image on the SP1000 substrate. The "01/DADMAC" coating had high color density before the soak, but based on visual inspection, the inks did not completely dry on the surface and were almost completely removed from both of the substrates during the soak. Further, based on visual inspection, the images were not distinct, there was significant color bleed and the images were not clear. The "01/DEA-EPI" coating had low color density on both substrates and the water resistance was poor. Based on visual inspection, there was no color bleed and the images were clear but appeared faded.

The present invention has been described with reference to the preferred embodiments. Obvious modifications and alterations will occur to others upon reading and understanding the detailed description. It is intended that the invention be construed as including all such modifications and alterations insofar as they come within the scope of appended claims or the equivalents thereof.

25

- 31 -

In the claims.

1. An ink recordable substrate coating composition having a pH less than 7 comprising:

- 5 (a) an aqueous polyurethane dispersion; and
(b) an aqueous solution of a nitrogen containing polymeric dye fixative compound.

2. The ink recordable substrate coating composition of
10 claim 1 wherein the polyurethane is selected from the group consisting of anionic polyurethanes, cationic polyurethanes, nonionic polyurethanes and mixtures thereof.

3. The ink recordable substrate coating composition of
15 claim 2 wherein the aqueous anionic polyurethane dispersion comprises one or more anionic polyurethanes selected from the group consisting of aromatic polyether polyurethanes, aliphatic polyether polyurethanes, aromatic polyester polyurethanes, aliphatic polyester polyurethanes, aromatic
20 polycaprolactam polyurethanes, and aliphatic polycaprolactam polyurethanes.

4. The ink recordable substrate coating composition of
claim 2 wherein the aqueous anionic polyurethane has one or
25 more acid groups selected from the group consisting of carboxylic acid, sulfonic acid and mixtures thereof.

5. The ink recordable substrate coating composition of
claim 1 wherein the aqueous solution of a nitrogen containing
30 polymeric dye fixative compound comprises a polymer comprising monomer residues derived from one or more nitrogen containing monomers selected from the group consisting of:

- 32 -

- 5 wherein R^1 is selected independently for each occurrence in each structure from the group consisting of H and C_1 to C_3 aliphatic; R^2 is independently for each structure a divalent linking group selected from the group consisting of C_2 to C_{20} aliphatic hydrocarbon, polyethylene glycol and polypropylene glycol; R^3 is independently for each occurrence in each
- 10 structure selected from the group consisting of H, C_1 to C_{22} aliphatic hydrocarbon and a residue from the reaction of the nitrogen with epichlorohydrin; Z is selected from the group consisting of $-\text{O}-$ and $-\text{NR}^4-$, where R^4 is selected from the

- 33 -

group consisting of H and CH₃; and X is selected from the group consisting of halides and methylsulfate.

6. The ink recordable substrate coating composition of claim 1 wherein the aqueous polyurethane dispersion is present at from 10 to 70 percent by weight of the ink recordable substrate coating composition and the aqueous solution of a nitrogen containing polymeric dye fixative compound is present at from 30 to 90 percent by weight of the ink recordable substrate coating composition.

7. The ink recordable substrate coating composition of claim 5 wherein the nitrogen containing monomer is one or more selected from the group consisting of dimethyl aminoethyl (meth)acrylate, (meth)acryloyloxyethyl trimethyl ammonium halides, (meth)acryloyloxyethyl trimethyl ammonium methylsulfate, dimethyl aminopropyl (meth)acrylamide, (meth)acrylamidopropyl trimethyl ammonium halides, (meth)acrylamidopropyl trimethyl ammonium methylsulfate, aminoalkyl (meth)acrylamides where the amine is reacted with epichlorohydrin, diallyl amine, methyl diallyl amine, and diallyl dimethyl ammonium halides.

8. The ink recordable substrate coating composition of claim 3 wherein the anionic polyurethane is one or more selected from the group consisting of aromatic polyether polyurethanes, aliphatic polyether polyurethanes, aromatic polyester polyurethanes, and aliphatic polyester polyurethanes.

9. The ink recordable substrate coating composition of claim 1 wherein the total resin solids is from 1 to 35 wt.% based on the total weight of the ink recordable substrate coating composition.

10. The ink recordable substrate coating composition of claim 1 wherein the viscosity of the ink recordable substrate coating composition is less than 500 cps.

5 11. The ink recordable substrate coating composition of claim 1 prepared by mixing the nitrogen containing polymeric dye fixative compound (b) into the aqueous polyurethane dispersion (a).

10 12. An ink recordable substrate coating composition having a pH less than 7 formed by adding (a) an aqueous solution of a polymeric nitrogen containing dye fixative compound to (b) an aqueous anionic polyurethane dispersion comprising one or more anionic polyurethanes selected from the
15 group consisting of aromatic polyether polyurethanes, aliphatic polyether polyurethanes, aromatic polyester polyurethanes, aliphatic polyester polyurethanes, aromatic polycaprolactam polyurethanes, and aliphatic polycaprolactam polyurethanes; wherein the total resin solids is from 1 to 35
20 wt.% based on the total weight of the ink recordable substrate coating composition and the viscosity of the ink recordable substrate coating composition is less than 500 cps.

25 13. The ink recordable substrate coating composition of claim 12 wherein the aqueous solution of a polymeric nitrogen containing dye fixative compound comprises a polymer comprising monomer residues derived from one or more nitrogen containing monomers selected from the group consisting of:

- 35 -

- 5 wherein R^1 is selected independently for each occurrence in each structure from the group consisting of H and C_1 to C_3 aliphatic; R^2 is independently for each structure a divalent linking group selected from the group consisting of C_2 to C_{20} aliphatic hydrocarbon, polyethylene glycol and polypropylene glycol; R^3 is independently for each occurrence in each
- 10 structure selected from the group consisting of H, C_1 to C_{22} aliphatic hydrocarbon and a residue from the reaction of the nitrogen with epichlorohydrin; Z is selected from the group consisting of $-\text{O}-$ and $-\text{NR}^4-$, where R^4 is selected from the

- 36 -

group consisting of H and CH₃; and X is selected from the group consisting of halides and methylsulfate.

14. The ink recordable substrate coating composition of claim 12 wherein the aqueous anionic polyurethane dispersion is present at from 10 to 70 percent by weight of the ink recordable substrate coating composition and the aqueous solution of a nitrogen containing polymeric dye fixative compound is present at from 30 to 90 percent by weight of the ink recordable substrate coating composition.

15. The ink recordable substrate coating composition of claim 13 wherein the nitrogen containing monomer is one or more selected from the group consisting of dimethyl aminoethyl (meth)acrylate, (meth)acryloyloxyethyl trimethyl ammonium halides, (meth)acryloyloxyethyl trimethyl ammonium methylsulfate, dimethyl aminopropyl (meth)acrylamide, (meth)acrylamidopropyl trimethyl ammonium halides, (meth)acrylamidopropyl trimethyl ammonium methylsulfate, aminoalkyl (meth)acrylamides where the amine is reacted with epichlorohydrin, diallyl amine, methyl diallyl amine, and diallyl dimethyl ammonium halides.

16. The ink recordable substrate coating composition of claim 12 wherein the nitrogen containing polymeric dye fixative compound is a polyamide amine reacted with epichlorohydrin.

17. The ink recordable substrate coating composition of claim 12 wherein the anionic polyurethane is one or more selected from the group consisting of aromatic polyether polyurethanes, aliphatic polyether polyurethanes, aromatic polyester polyurethanes, and aliphatic polyester polyurethanes.

- 37 -

18. A method of coating an ink recordable substrate comprising:

(a) providing an ink recordable substrate having a top surface and a bottom surface;

5 (b) providing a coating composition having a pH less than 7 comprising:

(i) an aqueous polyurethane dispersion; and

(ii) an aqueous solution of a nitrogen containing polymeric dye fixative compound;

10 (c) applying the coating composition to at least one side of the ink recordable substrate.

19. The method of claim 18 wherein the ink recordable substrate comprises a microporous substrate having a top
15 surface and a bottom surface and comprising:

(a) a matrix comprising a polyolefin;

(b) a finely divided particulate siliceous filler distributed throughout the matrix; and

(c) a network of interconnecting pores
20 communicating throughout the microporous substrate, said pores constituting at least about 35 percent by volume of said microporous substrate.

20. The method of claim 19 wherein the polyolefin
25 comprises one or both selected from the group consisting of a linear high molecular weight polyethylene having an intrinsic viscosity of at least 10 deciliters/gram and a linear high molecular weight polypropylene having an intrinsic viscosity of at least 5 deciliters/gram.

30

21. The method of claim 19 wherein the siliceous filler constitutes from 50 percent to 90 percent by weight of the microporous substrate.

- 38 -

22. The method of claim 18 wherein the ink recordable substrate has a porosity of not more than 20,000 seconds/100cc air.

5 23. The method of claim 18 wherein the polyurethane in (b)(i) is selected from the group consisting of anionic polyurethanes, cationic polyurethanes, nonionic polyurethanes, and mixtures thereof.

10 24. The method of claim 23 wherein the aqueous anionic polyurethane dispersion comprises one or more anionic polyurethanes selected from the group consisting of aromatic polyether polyurethanes, aliphatic polyether polyurethanes, aromatic polyester polyurethanes, aliphatic polyester
15 polyurethanes, aromatic polycaprolactam polyurethanes, and aliphatic polycaprolactam polyurethanes.

25. The method of claim 23 wherein the aqueous anionic polyurethane has one or more acid groups selected from the
20 group consisting of carboxylic acid, sulfonic acid and mixtures thereof.

26. The method of claim 18 wherein the aqueous solution of a nitrogen containing polymeric dye fixative compound
25 comprises a polymer comprising monomer residues derived from one or more nitrogen containing monomers selected from the group consisting of:

- 39 -

wherein R^1 is selected independently for each occurrence in
 5 each structure from the group consisting of H and C_1 to C_3
 aliphatic; R^2 is independently for each structure a divalent
 linking group selected from the group consisting of C_2 to C_{20}
 aliphatic hydrocarbon, polyethylene glycol and polypropylene
 glycol; R^3 is independently for each occurrence in each
 10 structure selected from the group consisting of H, C_1 to C_{22}
 aliphatic hydrocarbon and a residue from the reaction of the
 nitrogen with epichlorohydrin; Z is selected from the group
 consisting of $-\text{O}-$ and $-\text{NR}^4-$, where R^4 is selected from the
 group consisting of H and CH_3 ; and X is selected from the group
 15 consisting of halides and methylsulfate.

27. The method of claim 18 wherein the aqueous
 polyurethane dispersion is present at from 10 to 70 percent by
 weight of the ink recordable substrate coating composition and
 20 the aqueous solution of a nitrogen containing polymeric dye

- 40 -

fixative compound is present at from 30 to 90 percent by weight of the coating composition.

28. The method of claim 26 wherein the nitrogen
5 containing monomer is one or more selected from the group
consisting of dimethyl aminoethyl (meth)acrylate,
(meth)acryloyloxyethyl trimethyl ammonium halides,
(meth)acryloyloxyethyl trimethyl ammonium methylsulfate,
dimethyl aminopropyl (meth)acrylamide, (meth)acrylamidopropyl
10 trimethyl ammonium halides, (meth)acrylamidopropyl trimethyl
ammonium methylsulfate, aminoalkyl (meth)acrylamides where the
amine is reacted with epichlorohydrin, diallyl amine, methyl
diallyl amine, and diallyl dimethyl ammonium halides.

15 29. The method of claim 18 wherein the nitrogen
containing polymeric dye fixative compound is a polyamide
amine reacted with epichlorohydrin.

20 30. The method of claim 24 wherein the anionic
polyurethane is one or more selected from the group consisting
of aromatic polyether polyurethanes, aliphatic polyether
polyurethanes, aromatic polyester polyurethanes, and aliphatic
polyester polyurethanes.

25 31. The method of claim 18 wherein the total resin
solids is from 1 to 35 wt.% based on the total weight of the
coating composition.

30 32. The method of claim 18 wherein the viscosity of the
coating composition is less than 500 cps.

33. The method of claim 18 wherein the polyurethane
(b) (i) is an anionic polyurethane and the coating composition
is prepared by mixing the nitrogen containing polymeric dye

- 41 -

fixative compound (b) (ii) into the aqueous polyurethane dispersion (b) (i).

34. The method of claim 18 wherein the coating
5 composition is applied to both sides of the ink recordable substrate.

35. The method of claim 18 wherein the application of the coating composition comprises:

10 (a) applying the coating composition to the ink recordable substrate using a method selected from the group consisting of flexography, spraying, air knife coating, curtain coating, dipping, rod coating, blade coating, gravure, reverse roll, roller application, imbibing, size press,
15 printing, brushing, drawing, slot-die coating, and extrusion; and

(b) drying the coated ink recordable substrate by applying a temperature from ambient to 350°F.

20 36. A coated ink recordable substrate coated using the method of claim 18.

37. A method of coating a microporous substrate comprising:

25 (a) providing a microporous substrate having an upper surface and a lower surface comprising:

(i) a matrix comprising a polyolefin;

(ii) a finely divided particulate siliceous filler distributed throughout the matrix; and

30 (iii) a network of interconnecting pores communicating throughout the microporous substrate, said pores constituting at least about 35 percent by volume of said microporous substrate;

(b) providing a coating composition having a pH
35 less than 7 comprising the product formed by adding,

- 42 -

(i) an aqueous solution of a polymeric nitrogen containing dye fixative compound to,

(ii) an aqueous anionic polyurethane dispersion comprising one or more anionic polyurethanes
5 selected from the group consisting of aromatic polyether polyurethanes, aliphatic polyether polyurethanes, aromatic polyester polyurethanes, aliphatic polyester polyurethanes, aromatic polycaprolactam polyurethanes, and aliphatic polycaprolactam polyurethanes; wherein the total resin solids
10 is from 1 to 35 wt.% based on the total weight of the coating composition and the viscosity of the coating composition is less than 500 cps; and

(c) applying the coating composition to at least one surface of the microporous substrate by,

15 (i) applying the coating composition to the microporous substrate using a method selected from the group consisting of flexography, spraying, air knife coating, curtain coating, dipping, rod coating, blade coating, gravure, reverse roll, roller application, imbibing, size press,
20 printing, brushing, drawing, slot-die coating, and extrusion; and

(ii) drying the coated ink recordable substrate by applying a temperature from ambient to 350°F.

25 38. The method of claim 37 wherein the aqueous anionic polyurethane has one or more acid groups selected from the group consisting of carboxylic acid, sulfonic acid and mixtures thereof.

30 39. The method of claim 37 wherein the aqueous solution of a polymeric nitrogen containing dye fixative compound comprises a polymer comprising monomer residues derived from one or more nitrogen containing monomers selected from the group consisting of:

35

- 43 -

- 5 wherein R^1 is selected independently for each occurrence in each structure from the group consisting of H and C_1 to C_3 aliphatic; R^2 is independently for each structure a divalent linking group selected from the group consisting of C_2 to C_{20} aliphatic hydrocarbon, polyethylene glycol and polypropylene
- 10 glycol; R^3 is independently for each occurrence in each structure selected from the group consisting of H, C_1 to C_{22} aliphatic hydrocarbon and a residue from the reaction of the nitrogen with epichlorohydrin; Z is selected from the group consisting of -O- and - NR^4 -, where R^4 is selected from the

- 44 -

group consisting of H and CH₃; and X is selected from the group consisting of halides and methylsulfate.

40. The method of claim 37 wherein the aqueous anionic
5 polyurethane dispersion is present at from 10 to 70 percent by weight of the coating composition and the aqueous solution of a nitrogen containing polymeric dye fixative compound is present at from 30 to 90 percent by weight of the coating composition.

10

41. The method of claim 39 wherein the nitrogen
containing monomer is one or more selected from the group
consisting of dimethyl aminoethyl (meth)acrylate,
(meth)acryloyloxyethyl trimethyl ammonium halides,
15 (meth)acryloyloxyethyl trimethyl ammonium methylsulfate,
dimethyl aminopropyl (meth)acrylamide, (meth)acrylamidopropyl
trimethyl ammonium halides, (meth)acrylamidopropyl trimethyl
ammonium methylsulfate, aminoalkyl (meth)acrylamides where the
amine is reacted with epichlorohydrin, diallyl amine, methyl
20 diallyl amine, and diallyl dimethyl ammonium halides.

25

42. The method of claim 37 wherein the nitrogen
containing polymeric dye fixative compound is a polyamide
amine reacted with epichlorohydrin.

43. The method of claim 37 wherein the anionic
polyurethane is one or more selected from the group consisting
of aromatic polyether polyurethanes, aliphatic polyether
polyurethanes, aromatic polyester polyurethanes, and aliphatic
30 polyester polyurethanes.

44. The method of claim 37 wherein the polyolefin
comprises one or both selected from the group consisting of a
linear high molecular weight polyethylene having an intrinsic
35 viscosity of at least about 10 deciliters/gram and a linear

- 45 -

high molecular weight polypropylene having an intrinsic viscosity of at least about 5 deciliters/gram.

45. The method of claim 37 wherein the siliceous filler
5 constitutes from 50 percent to 90 percent by weight of the microporous substrate.

46. The method of claim 37 wherein the microporous
substrate has a porosity of not more than 20,000 seconds/100cc
10 air.

47. A coated microporous substrate coated using the
method of claim 37.

15 48. A method of coating a microporous substrate comprising:

(a) providing a microporous substrate having
having an upper surface and a lower surface comprising:

(i) a matrix comprising a polyolefin;
20 (ii) a finely divided particulate siliceous
filler distributed throughout the matrix; and
(iv) a network of interconnecting pores
communicating throughout the microporous substrate, said pores
constituting at least about 35 percent by volume of said
25 microporous substrate;

(b) providing a coating composition having a pH
less than 7 comprising the product formed by adding,

(i) an aqueous solution of a polymeric
nitrogen containing dye fixative compound to,

30 (ii) an aqueous cationic polyurethane
dispersion; wherein the total resin solids is from 1 to 35
wt.% based on the total weight of the coating composition and
the viscosity of the coating composition is less than 500 cps;
and

- 46 -

(c) applying the coating composition to at least one side of the microporous substrate by,

(i) applying the coating composition to the microporous substrate using a method selected from the group consisting of flexography, spraying, air knife coating, curtain coating, dipping, rod coating, blade coating, gravure, reverse roll, roller application, imbibing, size press, printing, brushing, drawing, slot-die coating, and extrusion; and

(ii) drying the coated ink recordable substrate by applying a temperature from ambient to 350°F.

49. The method of claim 48 wherein the aqueous solution of a polymeric nitrogen containing dye fixative compound comprises a polymer comprising monomer residues derived from one or more nitrogen containing monomers selected from the group consisting of:

20

- 47 -

wherein R^1 is selected independently for each occurrence in each structure from the group consisting of H and C_1 to C_3 aliphatic; R^2 is independently for each structure a divalent linking group selected from the group consisting of C_2 to C_{20} aliphatic hydrocarbon, polyethylene glycol and polypropylene glycol; R^3 is independently for each occurrence in each structure selected from the group consisting of H, C_1 to C_{22} aliphatic hydrocarbon and a residue from the reaction of the nitrogen with epichlorohydrin; Z is selected from the group consisting of $-\text{O}-$ and $-\text{NR}^4-$, where R^4 is selected from the group consisting of H and CH_3 ; and X is selected from the group consisting of halides and methylsulfate.

15

50. The method of claim 48 wherein the aqueous cationic polyurethane dispersion is present at from 10 to 70 percent by weight of the coating composition and the aqueous solution of a nitrogen containing polymeric dye fixative compound is present at from 30 to 90 percent by weight of the coating composition.

20

51. The method of claim 49 wherein the nitrogen containing monomer is one or more selected from the group consisting of dimethyl aminoethyl (meth)acrylate, (meth)acryloyloxyethyl trimethyl ammonium halides, (meth)acryloyloxyethyl trimethyl ammonium methylsulfate,

25

- 48 -

dimethyl aminopropyl (meth)acrylamide, (meth)acrylamidopropyl trimethyl ammonium halides, (meth)acrylamidopropyl trimethyl ammonium methylsulfate, aminoalkyl (meth)acrylamides where the amine is reacted with epichlorohydrin, diallyl amine, methyl diallyl amine, and diallyl dimethyl ammonium halides.

52. The method of claim 48 wherein the nitrogen containing polymeric dye fixative compound is a polyamide amine reacted with epichlorohydrin.

10

53. The method of claim 48 wherein the polyolefin comprises one or both selected from the group consisting of a linear high molecular weight polyethylene having an intrinsic viscosity of at least about 10 deciliters/gram and a linear high molecular weight polypropylene having an intrinsic viscosity of at least about 5 deciliters/gram.

54. The method of claim 48 wherein the siliceous filler constitutes from 50 percent to 90 percent by weight of the microporous substrate.

20

55. The method of claim 48 wherein the microporous substrate has a porosity of not more than 20,000 seconds/100cc air.

25

56. A coated microporous substrate coated using the method of claim 48.

57. A coated microporous substrate comprising:

(a) a microporous substrate having an upper surface and a lower surface comprising:

(i) a matrix comprising a polyolefin;
(ii) a finely divided particulate siliceous filler distributed throughout the matrix; and

30

- 49 -

(iii) a network of interconnecting pores communicating throughout the microporous substrate, said pores constituting at least about 35 percent by volume of said microporous substrate; and

5 (b) a coating layer on at least one surface of the microporous substrate, said coating layer comprising:

(i) a polymeric nitrogen containing dye fixative compound; and

10 (ii) one or more polyurethanes selected from the group consisting of anionic polyurethanes, cationic polyurethanes, nonionic polyurethanes, and mixtures thereof.

58. The coated microporous substrate of claim 57 wherein the polyurethane is an anionic polyurethane, and the aqueous
15 anionic polyurethane has one or more acid groups selected from the group consisting of carboxylic acid, sulfonic acid and mixtures thereof.

59. The coated microporous substrate of claim 57 wherein
20 the polymeric nitrogen containing dye fixative compound comprises a polymer comprising monomer residues derived from one or more nitrogen containing monomers selected from the group consisting of:

- 50 -

wherein R^1 is selected independently for each occurrence in
 5 each structure from the group consisting of H and C_1 to C_3
 aliphatic; R^2 is independently for each structure a divalent
 linking group selected from the group consisting of C_2 to C_{20}
 aliphatic hydrocarbon, polyethylene glycol and polypropylene
 glycol; R^3 is independently for each occurrence in each
 10 structure selected from the group consisting of H, C_1 to C_{22}
 aliphatic hydrocarbon and a residue from the reaction of the
 nitrogen with epichlorohydrin; Z is selected from the group
 consisting of $-O-$ and $-NR^4-$, where R^4 is selected from the
 group consisting of H and CH_3 ; and X is selected from the group
 15 consisting of halides and methylsulfate.

60. The coated microporous substrate of claim 57 wherein
 the polyurethane is present at from 10 to 70 percent by weight
 of the coating layer and the nitrogen containing polymeric dye
 20 fixative compound is present at from 30 to 90 percent by
 weight of the coating layer.

- 51 -

61. The coated microporous substrate of claim 59 wherein the nitrogen containing monomer is one or more selected from the group consisting of dimethyl aminoethyl (meth)acrylate, (meth)acryloyloxyethyl trimethyl ammonium halides, (meth)acryloyloxyethyl trimethyl ammonium methylsulfate, dimethyl aminopropyl (meth)acrylamide, (meth)acrylamidopropyl trimethyl ammonium halides, (meth)acrylamidopropyl trimethyl ammonium methylsulfate, aminoalkyl (meth)acrylamides where the amine is reacted with epichlorohydrin, diallyl amine, methyl diallyl amine, and diallyl dimethyl ammonium halides.

62. The coated microporous substrate of claim 57 wherein the nitrogen containing polymeric dye fixative compound is a polyamide amine reacted with epichlorohydrin.

63. The coated microporous substrate of claim 58 wherein the anionic polyurethane is one or more selected from the group consisting of aromatic polyether polyurethanes, aliphatic polyether polyurethanes, aromatic polyester polyurethanes, and aliphatic polyester polyurethanes.

64. The coated microporous substrate of claim 57 wherein the polyolefin comprises one or both selected from the group consisting of a linear high molecular weight polyethylene having an intrinsic viscosity of at least about 10 deciliters/gram and a linear high molecular weight polypropylene having an intrinsic viscosity of at least about 5 deciliters/gram.

65. The coated microporous substrate of claim 57 wherein the siliceous filler constitutes from 50 percent to 90 percent by weight of the microporous substrate.

- 52 -

66. The coated microporous substrate of claim 57 wherein the coating layer penetrates into at least the first 1 micron of the surface of the microporous substrate.

5 67. The coated microporous substrate of claim 57 wherein the microporous substrate has a thickness of from 0.5 to 100 mils.

10 68. The coated microporous substrate of claim 57 wherein the coat weight is from 0.001 g/m² to 50 g/m².

15 69. The coated microporous substrate of claim 57 wherein the microporous substrate (a) has a porosity of not more than 20,000 seconds/100cc air.
